

## 1. Lua program execution function

Lua is a programming language similar to Python and JavaScript. Its syntax is easier and more user-friendly than the macros provided by the HMI. You can use simple instructions to complete complicated computing and develop variable functions, as well as programming the functions on your own, which makes the programming more flexible and easier to meet the application requirements.

The Lua program runs repeatedly during the HMI operation, which is similar to the HMI Clock macro and can run with other HMI macros at the same time without affecting the execution efficiency of each.

The Lua program editing interface and the IDE (Integrated Development Environment) are similar. In addition to the program editing function, it has a debug function that allows you to run the program on the HMI or simulate online (with a simulator) to check if the Lua program is suitable for the circumstance. The debug function can set the breakpoint, run the code line by line, as well as monitor the variables for quick modification of the program.

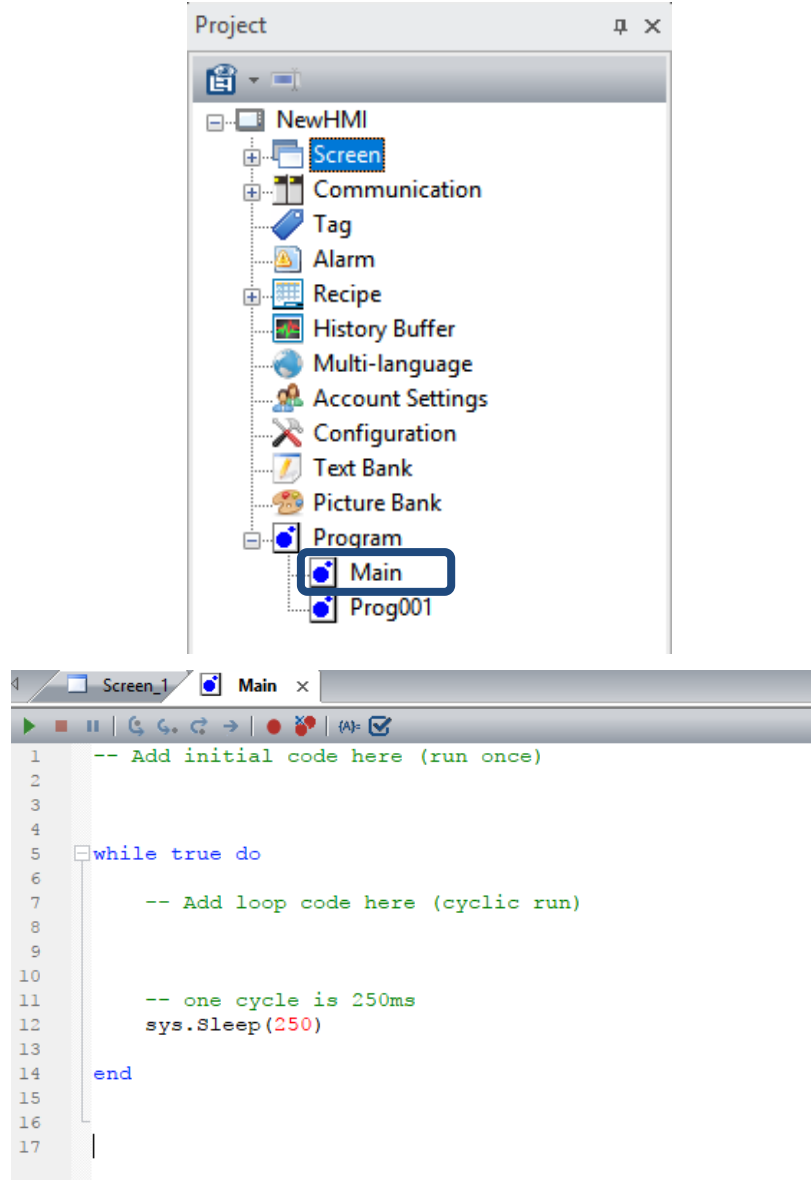

Please refer to Table 1.1 Lua programming example.

Table 1.1 Lua programming example

### 1. Lua programming

Step 1: double-click the [Main] tab in the DOPSoft project tree to enter the editing interface.

Edit [Main]  
program

```
1  -- Add initial code here (run once)
2
3
4
5  while true do
6
7      -- Add loop code here (cyclic run)
8
9
10
11     -- one cycle is 250ms
12     sys.Sleep(250)
13
14 end
15
16
17
```

## 1. Lua programming

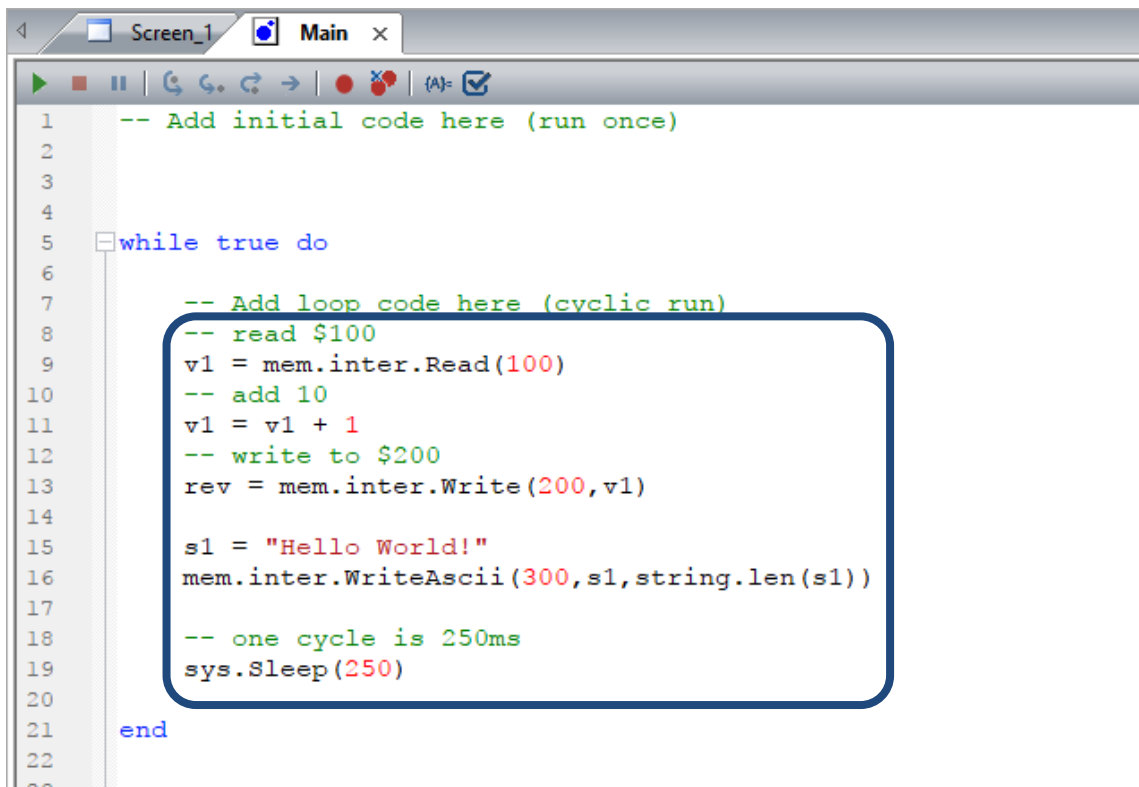

Step 2: add the following string to the [Main] program.

This program reads the value from \$100 and write this value plus 1 to \$200. Next, write the string "Hello World!" to \$300.

```
-- read $100
v1 = mem.inter.Read(100)
-- add 10
v1 = v1 + 1
-- write to $200
rev = mem.inter.Write(200,v1)

s1 = "Hello World!"
mem.inter.WriteAscii(300,s1,string.len(s1))
```

Edit [Main]  
program

```
1  -- Add initial code here (run once)
2
3
4
5  while true do
6
7      -- Add loop code here (cyclic run)
8      -- read $100
9      v1 = mem.inter.Read(100)
10     -- add 10
11     v1 = v1 + 1
12     -- write to $200
13     rev = mem.inter.Write(200,v1)
14
15     s1 = "Hello World!"
16     mem.inter.WriteAscii(300,s1,string.len(s1))
17
18     -- one cycle is 250ms
19     sys.Sleep(250)
20
21 end
```

## 1. Lua programming

Go to Screen\_1 to create two Numeric Entry elements with the read addresses as \$100 and \$200 respectively. Then, create one Character Entry element with the read address as \$300 and the string length as 12.

Edit HMI screen

Step 1: download this project to the HMI. The display is as follows after HMI power-on.

Execution results

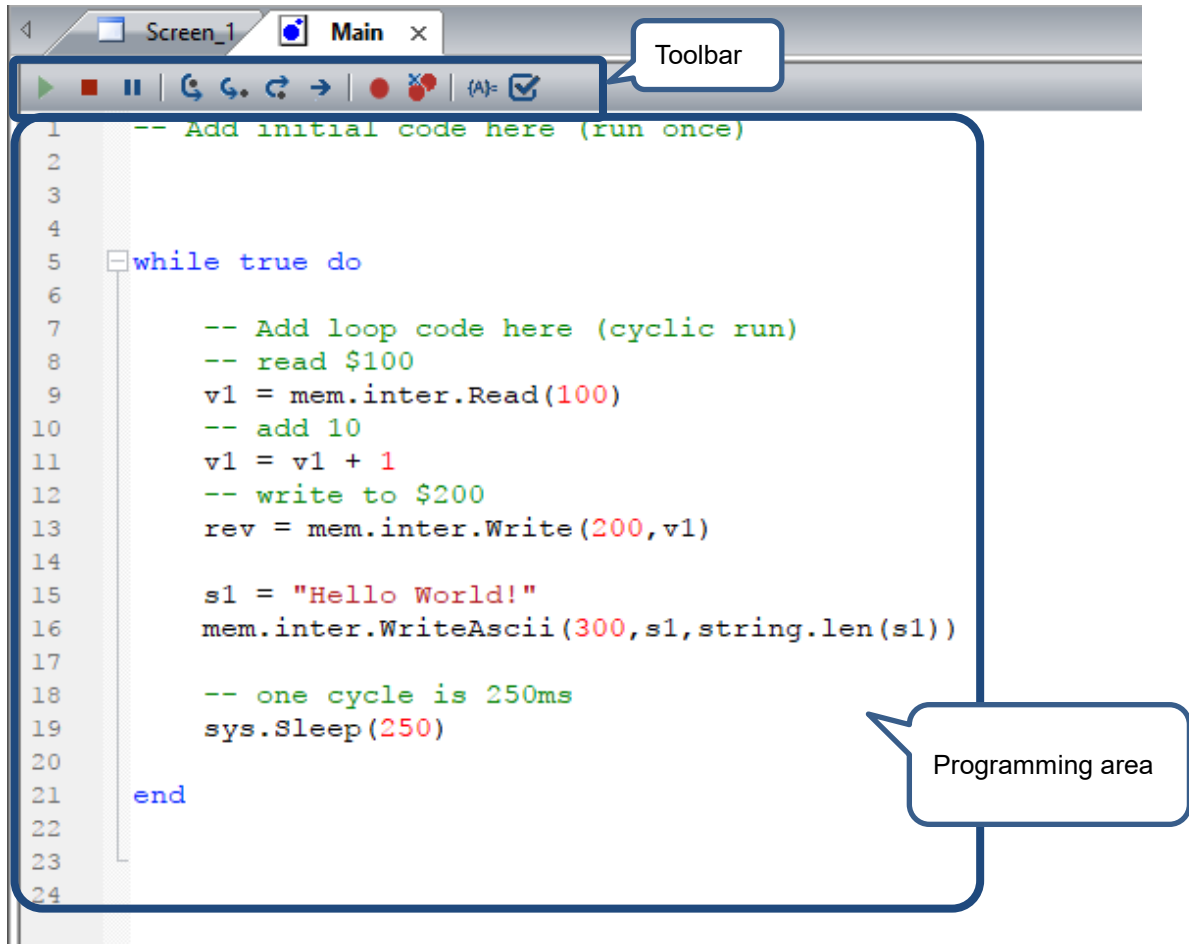

Step 2: change the value of \$100 to 95, and the value of \$200 changes to 96 immediately.

## 1.1 Lua program window

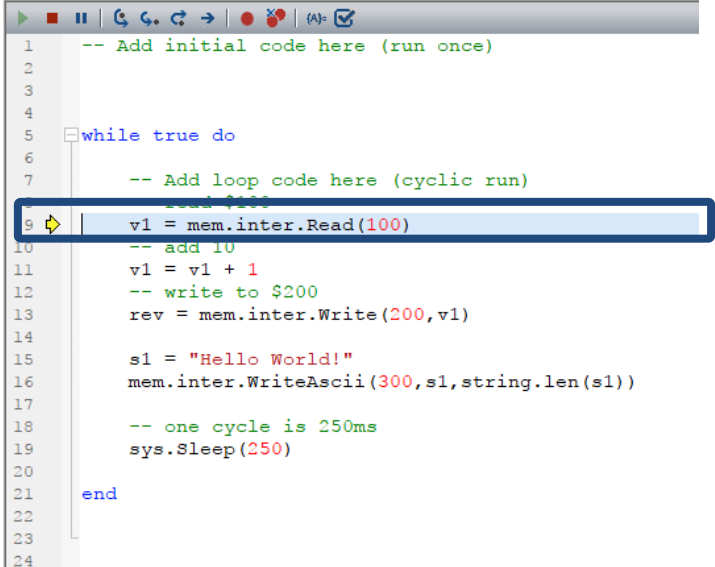

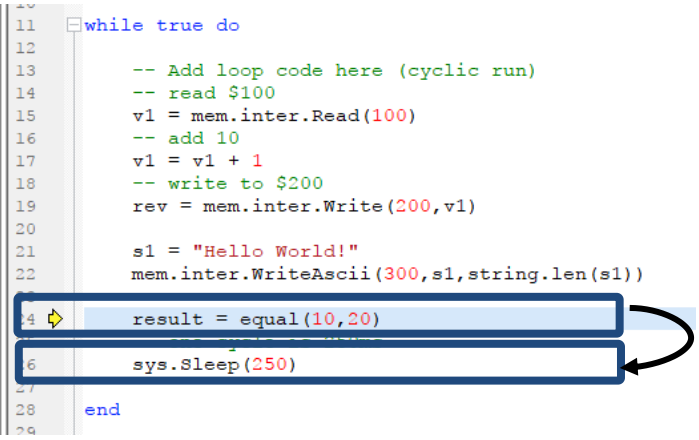

### 1.1.1 Lua programming window

Double-click on the Lua Program to open the Lua programming window as shown in the figure below.

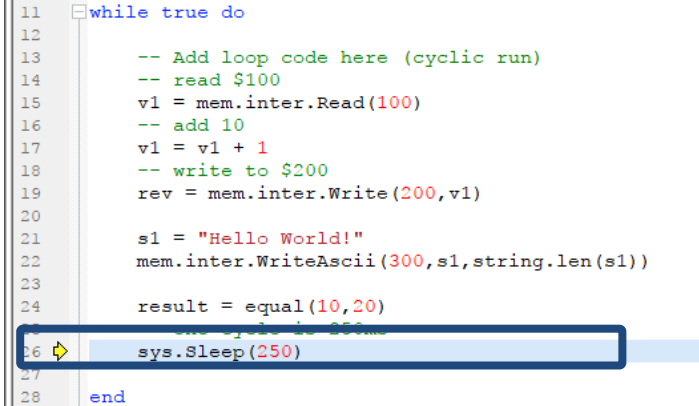

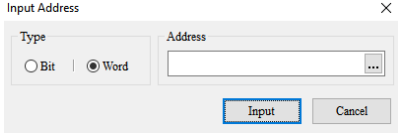

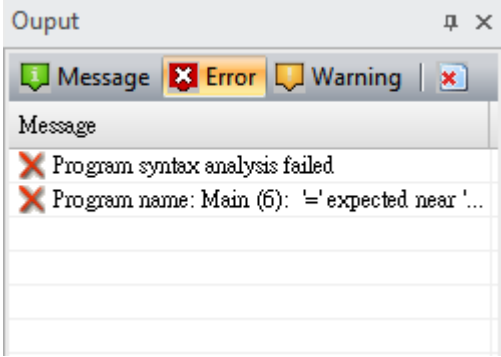

Toolbar function description for the Lua programming window is as follows:

Toolbar for the Lua programming window			
Symbol	Name	Hotkey	Description
	Start online program debugging	F5	Enable online debugging of the Lua program; the debugging target can be the HMI or simulator.
	Stop program debugging	Shift+F5	Stop the current Lua program in execution.

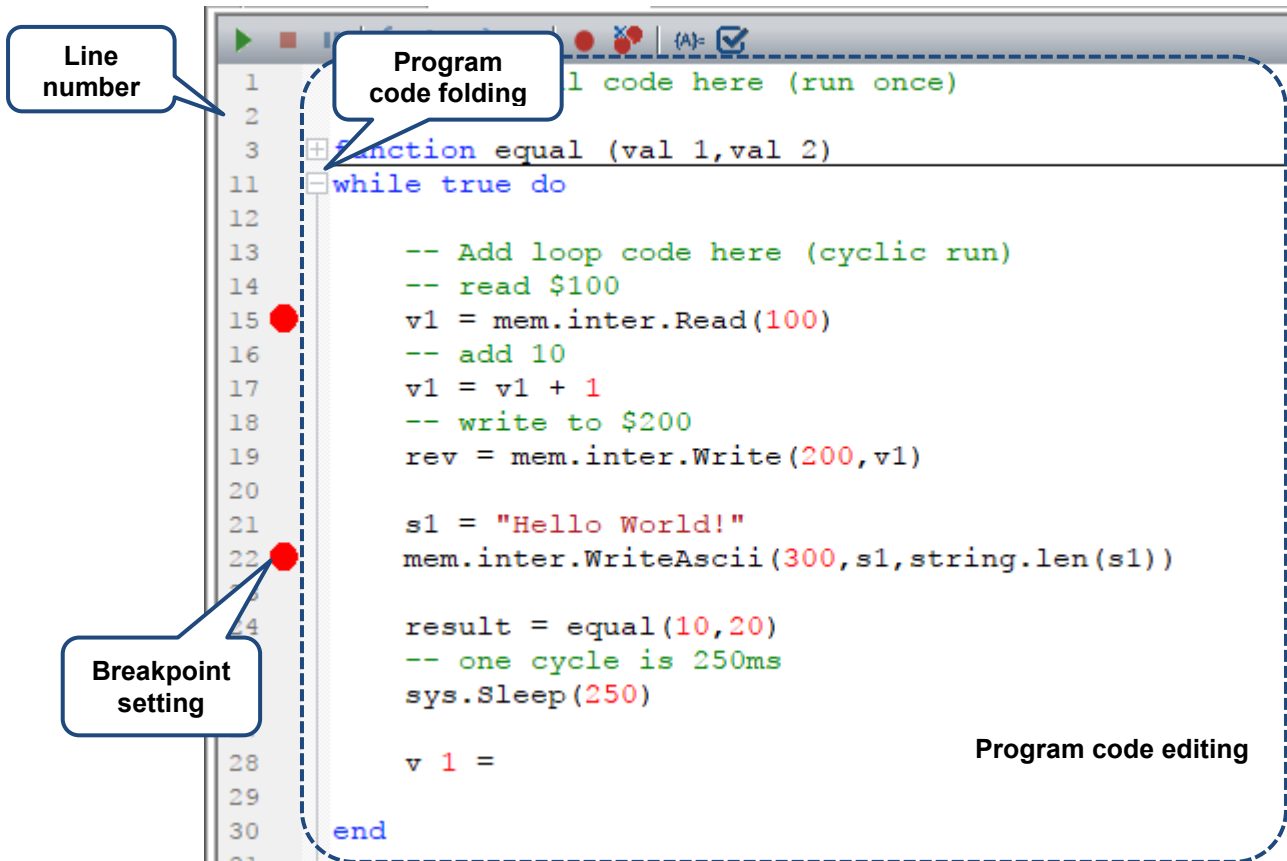

Toolbar for the Lua programming window			
Symbol	Name	Hotkey	Description
	Pause program debugging	-	<p>Pause the current Lua program in execution. When pausing, a yellow arrow points to the the next instruction to be executed.</p> 
	Run line by line	F10	<p>Run line by line. If the instruction to be executed is a function, this instruction is executed completely. In the example below, if you execute [Run line by line] at line 24, the program jumps to line 26.</p> 

Toolbar for the Lua programming window			
Symbol	Name	Hotkey	Description
	Jump into	F11	<p>When the instruction to be executed is a function, jump into the function to be executed. In the example below, line 24 “result = equal (10,20)” is a function, and its contents are in line 4 - 8. At line 24, if you execute “Jump into”, it jumps to execute line 4.</p> <pre> 11 while true do 12 13     -- Add loop code here (cyclic run) 14     -- read \$100 15     v1 = mem.inter.Read(100) 16     -- add 10 17     v1 = v1 + 1 18     -- write to \$200 19     rev = mem.inter.Write(200,v1) 20 21     s1 = "Hello World!" 22     mem.inter.WriteAscii(300,s1,string.len(s1)) 23 24     result = equal(10,20) 25     -- one cycle is 250ms 26     sys.Sleep(250) 27 28 end                 </pre> <p><b>Function contents</b></p> <pre> 3 function equal (val 1, val 2) 4     if val 1 == val 2 then 5         return 1 6     else 7         return 0 8     end 9 end                 </pre>
	Jump out	Shift+F11	<p>If the instructions in the function are in execution, jump out of the current function and go to the next instruction. As shown in the example below, the function contents are in line 4 - 8 that are called by line 24. Execute “Jump out” at line 4, it automatically runs line 4 - 8 and then goes to line 26.</p> <pre> 3 function equal (val 1, val 2) 4     if val 1 == val 2 then 5         return 1 6     else 7         return 0 8     end 9 end                 </pre> <p><b>Function contents</b></p>

Toolbar for the Lua programming window			
Symbol	Name	Hotkey	Description
			
	Resume	F5	Carry on executing the program after the program pauses.
	Breakpoint	F9	Set the breakpoint. During online debugging, the program execution pauses at a breakpoint. You can set multiple breakpoints at the same time.
	Delete all breakpoints		Delete all breakpoints in the program.
	Input Address		Open the Input Address window to input the bit or word address. 
	Program syntax check		Check if the Lua syntax in the project is correct. If there is any incorrect syntax, the output window displays the error description. 

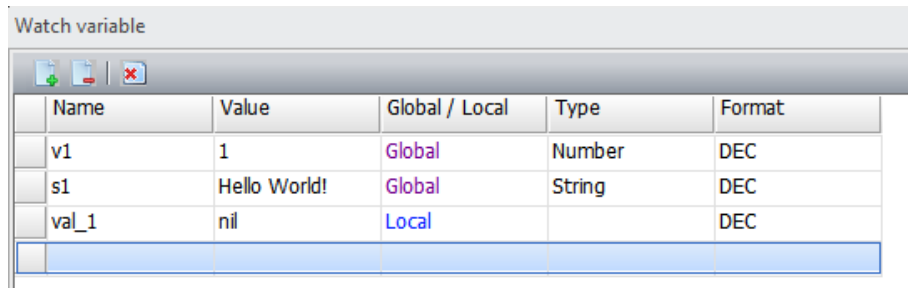

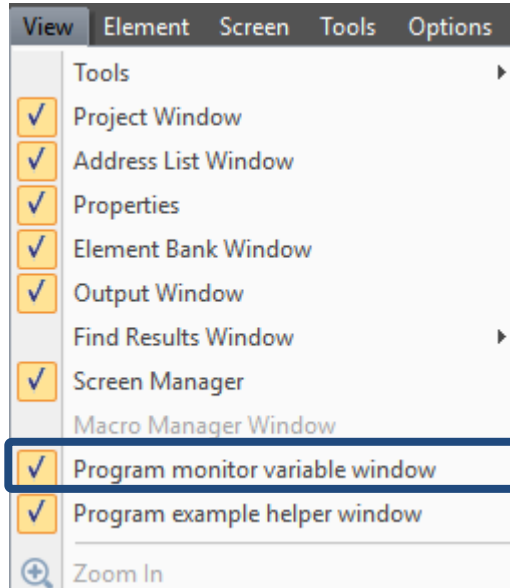

The Lua program editing window includes four parts, “Line number”, “Breakpoint setting”, “Program code folding”, and “program code editing”. You can click on [Breakpoint setting] to set or cancel the breakpoints.

### 1.1.2 Program monitor variable window

You can go to [View] to open the [Program monitor variable window]. This window allows you to monitor the Lua program execution results by specifying the variables. You can also change the variable in this window. For the operation example, please refer to the description in 3.2 Debug mode.

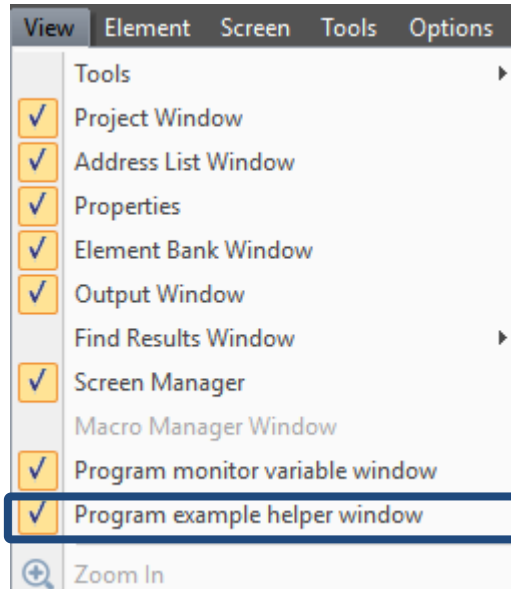

The image shows a window titled 'Watch variable' with a table of variables. The table has five columns: Name, Value, Global / Local, Type, and Format. The data rows are:

Name	Value	Global / Local	Type	Format
v1	1	Global	Number	DEC
s1	Hello World!	Global	String	DEC
val_1	nil	Local		DEC

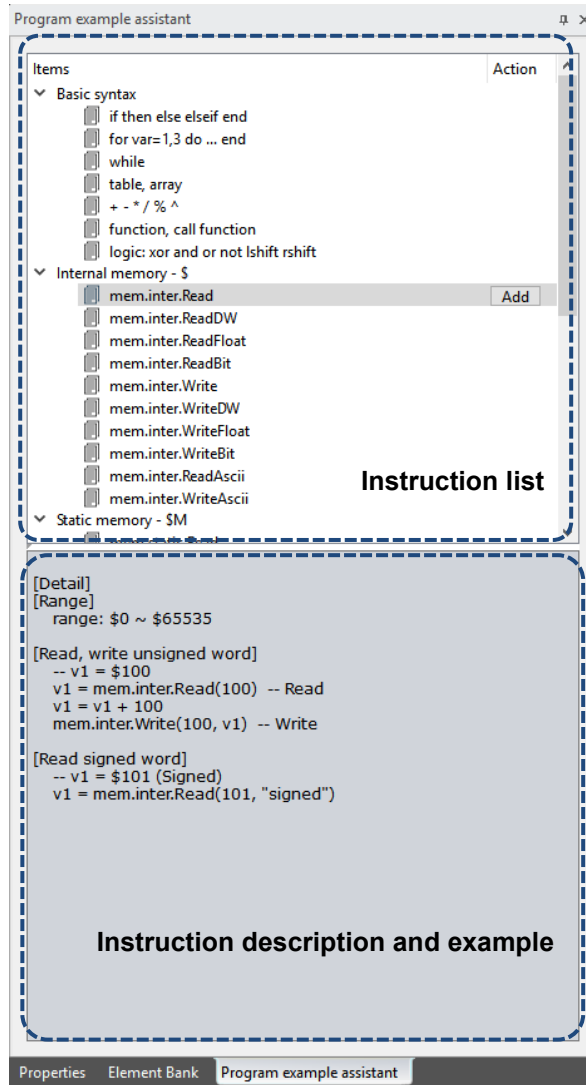

### 1.1.3 Program example helper window

You can go to [ View] to open the [Program example helper window].

This window lists all the Lua functions, including Basic syntax, Internal memory -\$ (for reading and writing), Static memory- \$M (internal register for non-volatile reading and writing), External link (reading / writing address for controller), File read / write / export / list, Math, Screen (for screen operation), String, System library, Serial port communication, Text encoding, and Utility.

The window has two parts, the upper part is the instruction list and the lower is the description and example of each instruction.

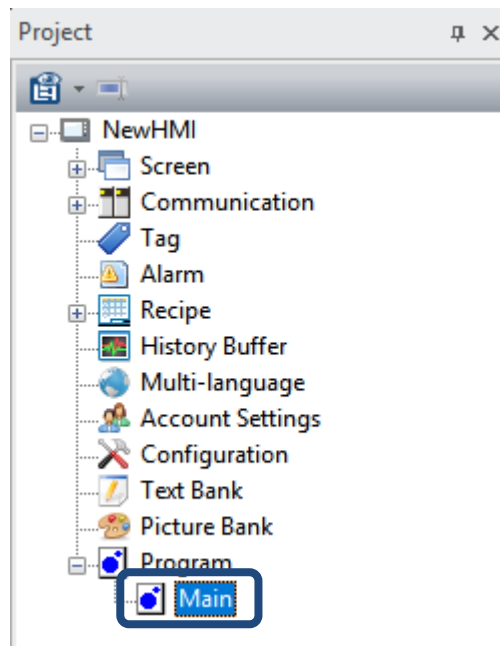

By clicking the **Add** button, you can add the instruction example in the Lua program. Please refer to Table 3.2 Example of adding Lua instruction.

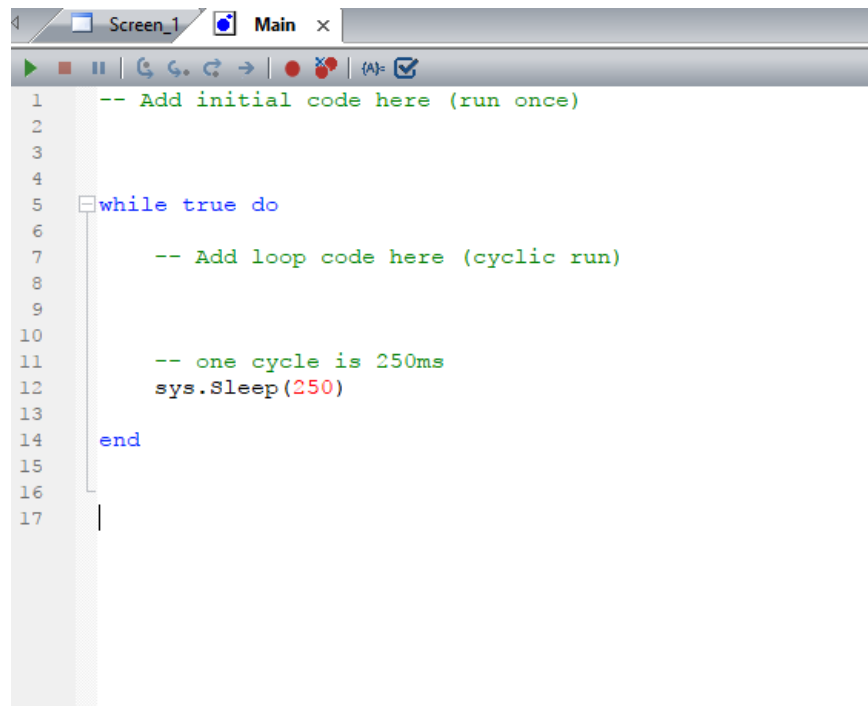

Table 1.2 Example of adding Lua instruction

### 1. Lua program

Step 1: double-click the [Main] tab in the DOPSoft project tree to enter the editing interface.

Open programming window

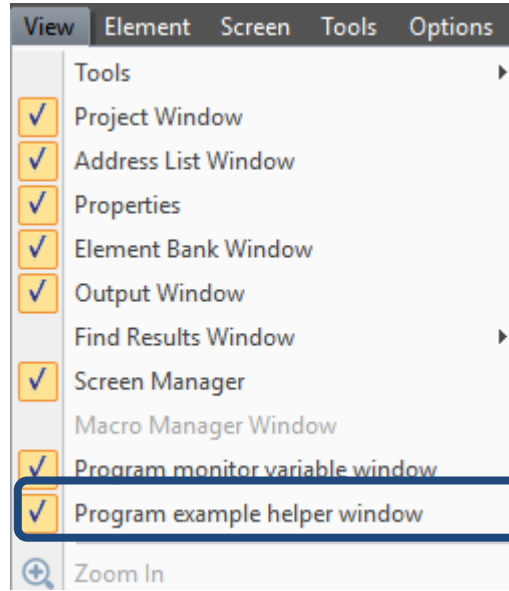

```
1  -- Add initial code here (run once)
2
3
4
5  while true do
6
7      -- Add loop code here (cyclic run)
8
9
10
11     -- one cycle is 250ms
12     sys.Sleep(250)
13
14 end
15
16
17
```

## 1. Lua program

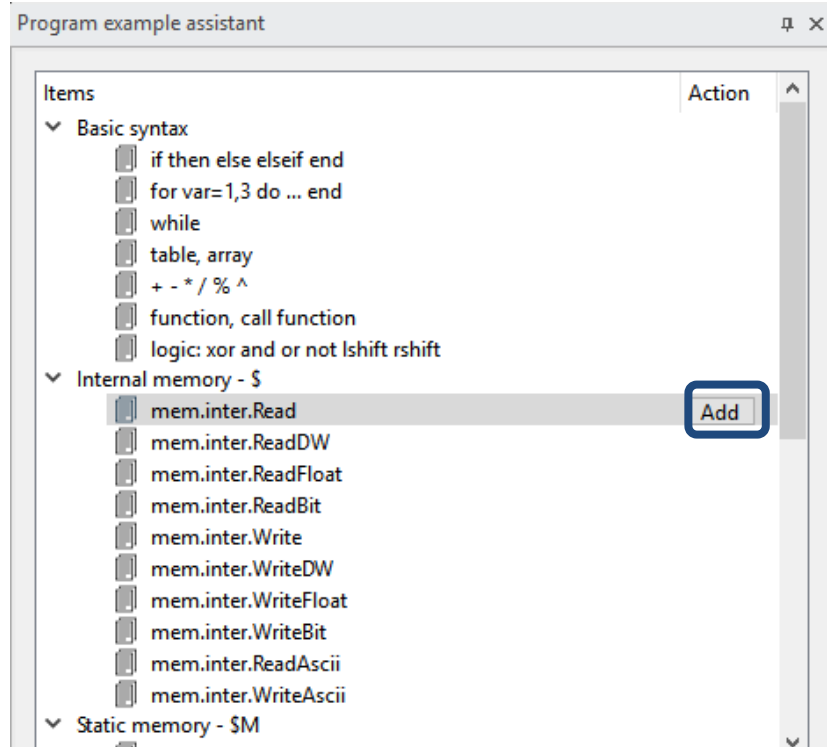

Open programming window

Step 2: go to [View] to open the [Program example helper window]

## 1. Lua program

Step 1: execute [Internal memory - \$] > [mem.inter.Read] > click the **Add** button.

Add Lua  
instruction  
mem.inter.Read

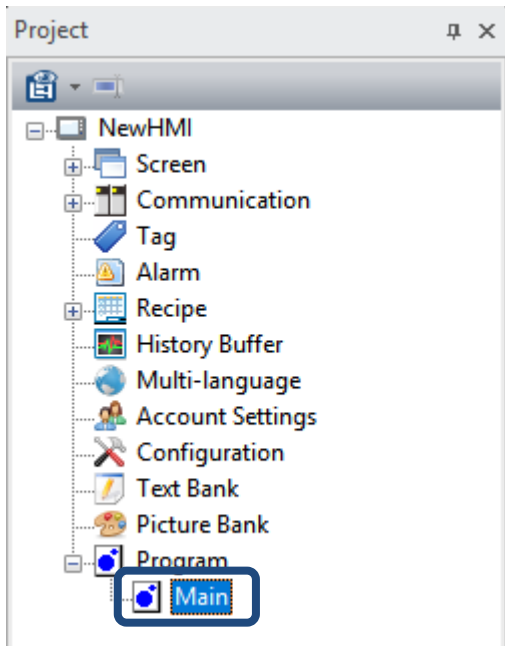

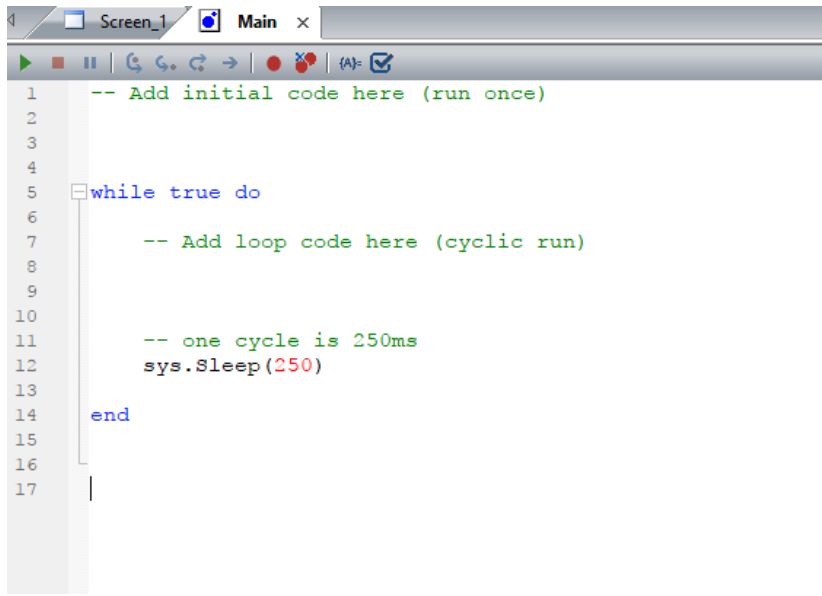

Step 2: a new instruction is added to the Lua program editing interface. Users can edit the program by referring to this example.

```
1  -- Add initial code here (run once)
2
10 while true do
11
12     -- Add loop code here (cyclic run)
13
14     v1 = mem.inter.Read(0)
15
16
17
18     -- one cycle is 250ms
19     sys.Sleep(250)
20
21
22 end
23
```

## 1.2 Debug mode

For the Lua program debugging method, please refer to Table 3.3 Lua program debugging example.

Table 1.3 Lua program debugging example

1. Lua programming	
Step 1: double-click the [Main] tab in the DOPSoft project tree to enter the editing interface.	
Edit [Main] program	 <pre>1  -- Add initial code here (run once) 2 3 4 5  while true do 6 7      -- Add loop code here (cyclic run) 8 9 10 11     -- one cycle is 250ms 12     sys.sleep(250) 13 14 end 15 16 17</pre>

## 1. Lua programming

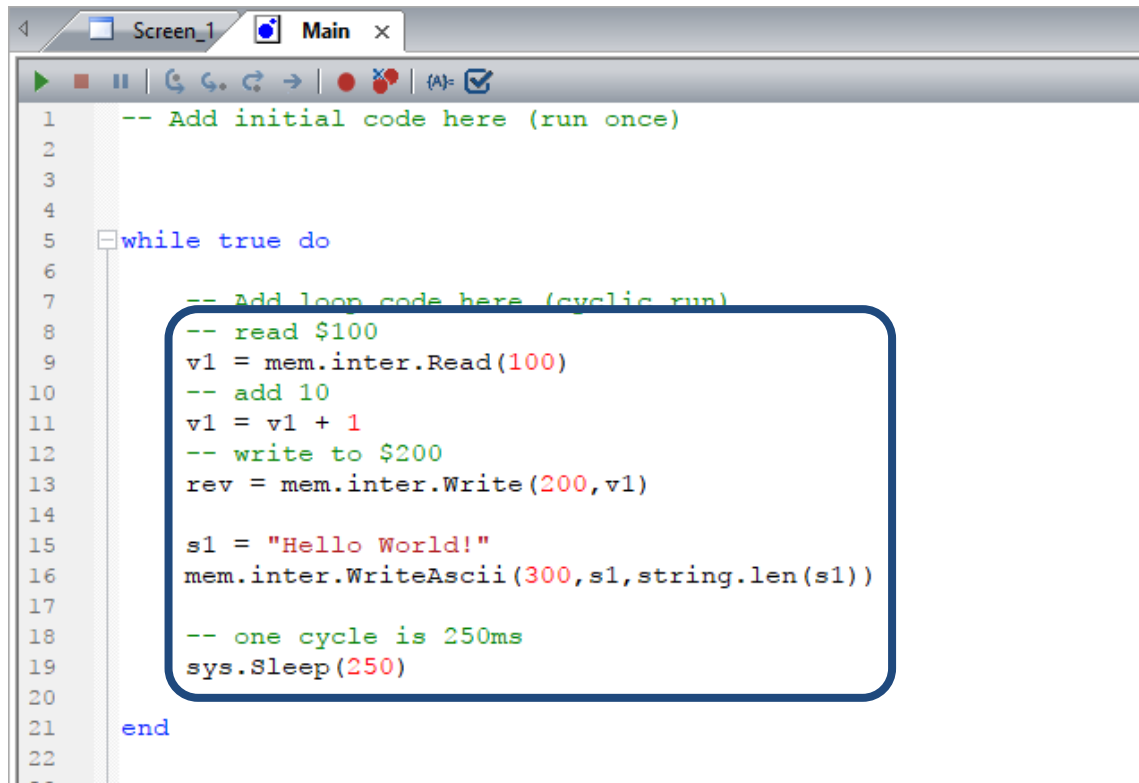

Step 2: add the following string to the [Main] program.

This program reads the value from \$100 and write this value plus 1 to \$200. Next, write the string "Hello World!" to \$300.

```
-- read $100
v1 = mem.inter.Read(100)
-- add 10
v1 = v1 + 1
-- write to $200
rev = mem.inter.Write(200,v1)

s1 = "Hello World!"
mem.inter.WriteAscii(300,s1,string.len(s1))
```

Edit [Main]  
program

```
1 -- Add initial code here (run once)
2
3
4
5 while true do
6
7 -- Add loop code here (cyclic run)
8 -- read $100
9 v1 = mem.inter.Read(100)
10 -- add 10
11 v1 = v1 + 1
12 -- write to $200
13 rev = mem.inter.Write(200,v1)
14
15 s1 = "Hello World!"
16 mem.inter.WriteAscii(300,s1,string.len(s1))
17
18 -- one cycle is 250ms
19 sys.Sleep(250)
20
21 end
22
23
```

## 1. Lua programming

Step 1: go to Screen\_1 to create two Numeric Entry elements and set the read addresses as \$100 and \$200 respectively. Then, create one Character Entry element with the read address as \$300 and the string length as 12.

Edit HMI screen

Step 2: create four numeric display elements on Screen\_1. Set the read address as NET1\_IP1, NET1\_IP2, NET1\_IP3, and NET1\_IP4 of Internal Parameter.

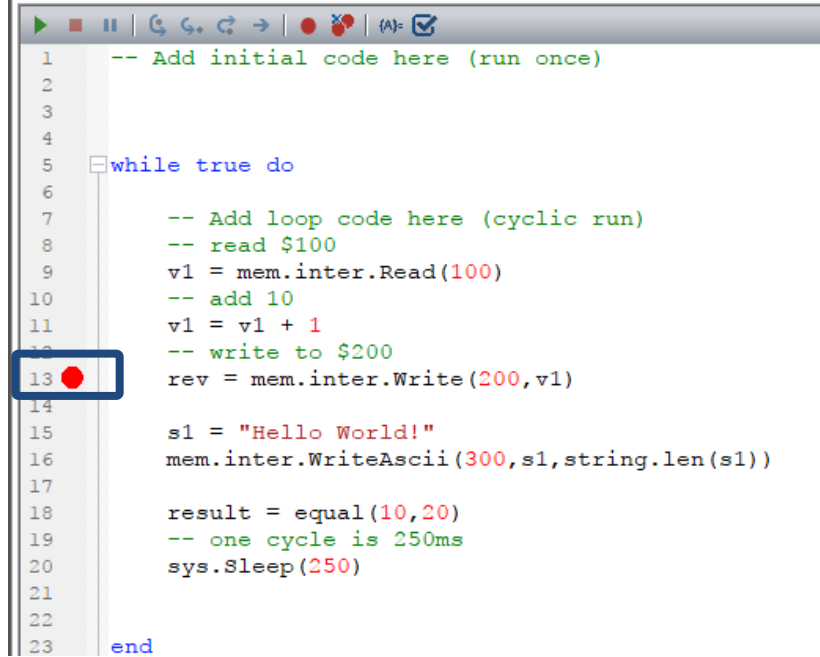

Execution results

Step 1: download the project to the HMI. The HMI display is as follows:

## 1. Lua programming

Step 2: click the left side of line 13 in the Lua program to set a breakpoint.

```

1  -- Add initial code here (run once)
2
3
4
5  while true do
6
7      -- Add loop code here (cyclic run)
8      -- read $100
9      v1 = mem.inter.Read(100)
10     -- add 10
11     v1 = v1 + 1
12     -- write to $200
13     rev = mem.inter.Write(200,v1)
14
15     s1 = "Hello World!"
16     mem.inter.WriteAscii(300,s1,string.len(s1))
17
18     result = equal(10,20)
19     -- one cycle is 250ms
20     sys.Sleep(250)
21
22
23 end
  
```

Execution results

Step 3: go to the Lua programming window to start online program debugging.

Step 4: specify the address as the HMI IP.

IP address ✕

Static IP

Auto Search Update

HMI	Model type	Source IP Address	Port

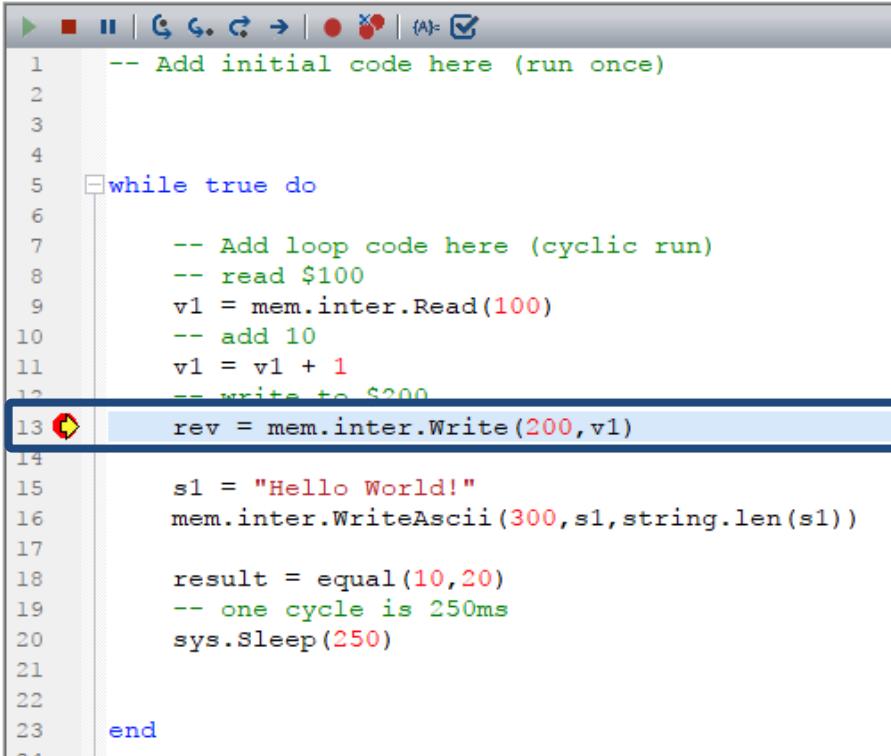

Password:  OK Cancel

IP :

## 1. Lua programming

Step 5: click **OK** and the Lua program starts running online. Then, it stops at line 13 where the breakpoint is placed.

Execution  
results

```
1  -- Add initial code here (run once)
2
3
4
5  while true do
6
7      -- Add loop code here (cyclic run)
8      -- read $100
9      v1 = mem.inter.Read(100)
10     -- add 10
11     v1 = v1 + 1
12     -- write to $200
13     rev = mem.inter.Write(200, v1)
14
15     s1 = "Hello World!"
16     mem.inter.WriteAscii(300, s1, string.len(s1))
17
18     result = equal(10, 20)
19     -- one cycle is 250ms
20     sys.Sleep(250)
21
22
23 end
```

## 1. Lua programming

Step 1: enter "v1" in the monitoring variable window.

Watch variable				
Name	Value	Global / Local	Type	Format
v1		Global	Number	DEC

Step 2: set 50 for \$100 on the HMI.

Monitoring variable

Step 3: click on the arrow button to carry on the execution in the Lua program editing window.

Step 4: Lua program runs and then stops again at line 13, where the breakpoint is placed. Because of the instructions of line 9 and 11, "v1" reads the value of \$100 and plus 1, then "v1" in the variable monitoring window is 51.

Watch variable				
Name	Value	Global / Local	Type	Format
v1	51	Global	Number	DEC

### 1.3 Subroutine execution

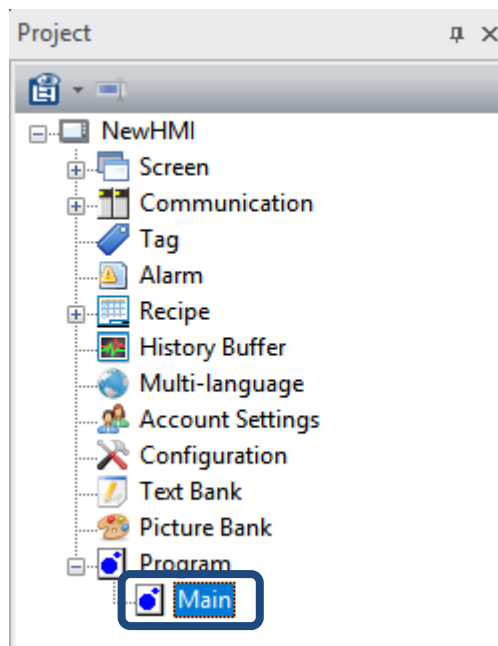

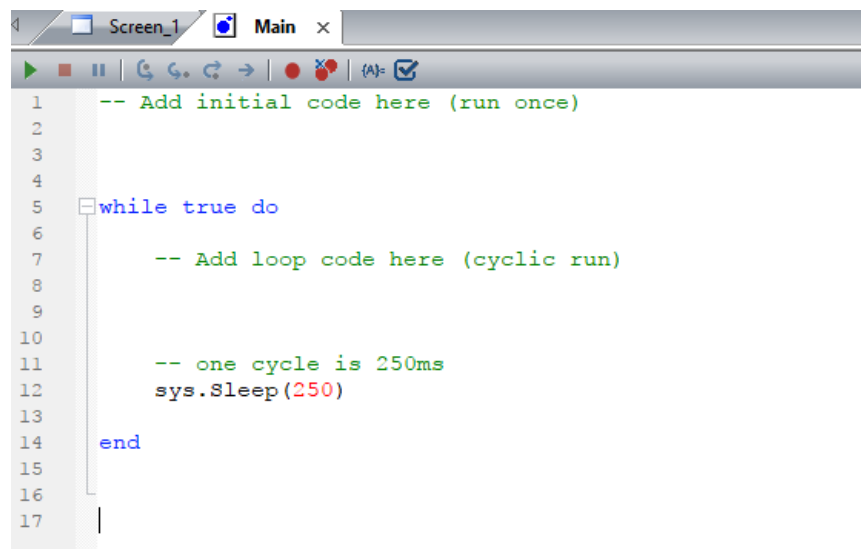

You can use subroutines in the Lua program to simplify the program for easy maintenance and development. In the Main program, you can use a “require” instruction to load the subroutine. Please refer to Table 1.4 Subroutine execution example.

Table 1.4 Subroutine execution example

## 1. Lua programming

Step 1: double-click [Main] in the DOPSoft project tree to enter the editing interface.

Edit [Main]  
program

The screenshot shows the 'Main' program editing interface. The code is as follows:

```

1  -- Add initial code here (run once)
2
3
4
5  while true do
6
7      -- Add loop code here (cyclic run)
8
9
10
11     -- one cycle is 250ms
12     sys.Sleep(250)
13
14 end
15
16
17

```

## 1. Lua programming

Step 2: add the following string to the [Main] program.

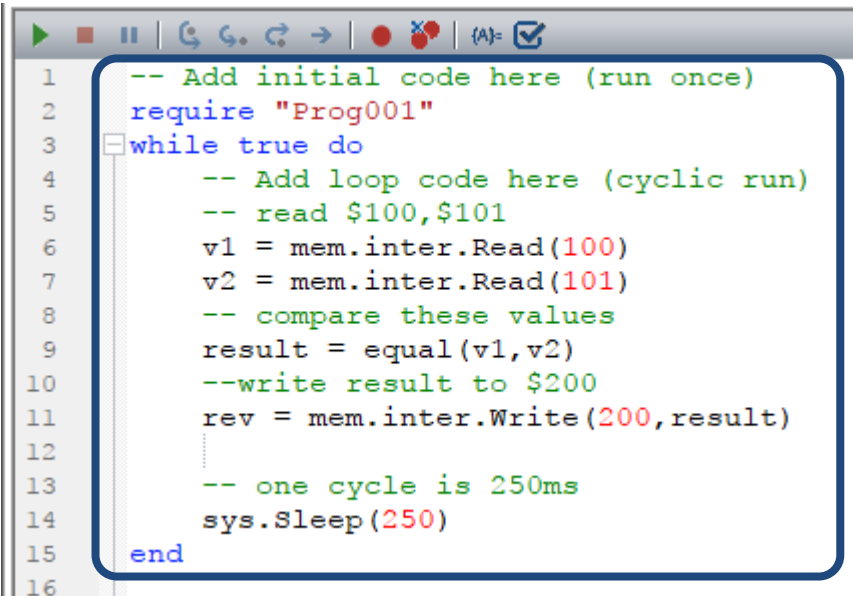

This part of the program compares the values of \$100 and \$101, and then write the result to \$200. If these two values are equal, the result is 1; if not, the result is 0.

[require "Prog001"] in the second line loads Prog001. The instruction in line 9 calls the function in the subroutine.

```
require "Prog001"
while true do
  -- Add loop code here (cyclic run)
  -- read $100,$101
  v1 = mem.inter.Read(100)
  v2 = mem.inter.Read(101)
  -- compare these values
  result = equal(v1,v2)
  --write result to $200
  rev = mem.inter.Write(200,result)

  -- one cycle is 250ms
  sys.Sleep(250)
end
```

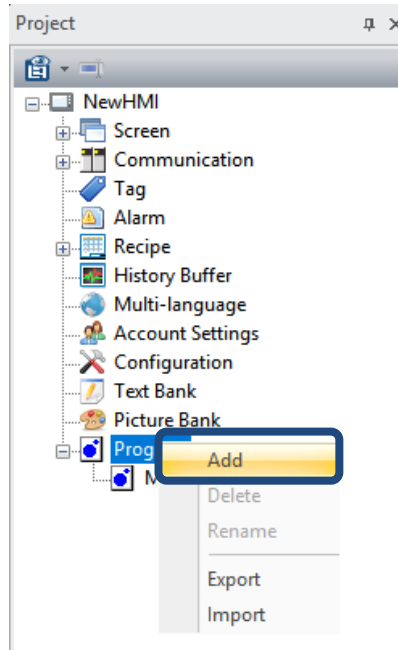

Edit [Main]  
program

```
1  -- Add initial code here (run once)
2  require "Prog001"
3  while true do
4      -- Add loop code here (cyclic run)
5      -- read $100,$101
6      v1 = mem.inter.Read(100)
7      v2 = mem.inter.Read(101)
8      -- compare these values
9      result = equal(v1,v2)
10     --write result to $200
11     rev = mem.inter.Write(200,result)
12     .....
13     -- one cycle is 250ms
14     sys.Sleep(250)
15 end
16
```

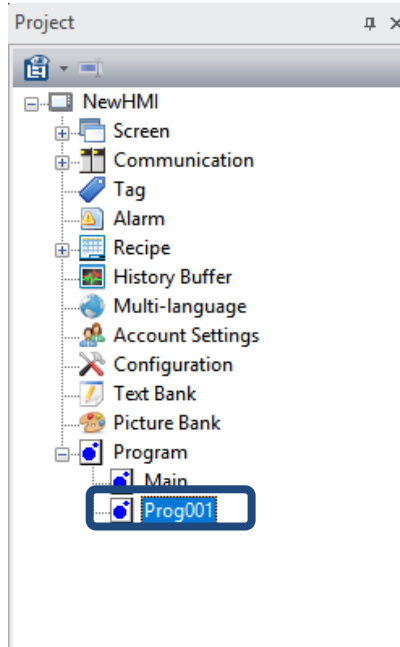

## 1. Lua programming

Step 1: right-click [Program] in the DOPSoft project tree to add a new program.

Edit sub-program

Step 2: double-click Prog001 to enter the editing interface.

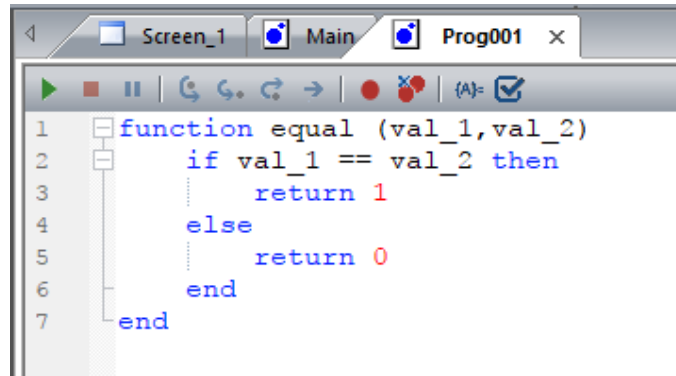

## 1. Lua programming

Step 3: add the string below to Prog001.

This program is a function and compares the two values to check if they are equal. If these two values are equal, the result is 1; if not, the result is 0.

```
function equal (val_1,val_2)
  if val_1 == val_2 then
    return 1
  else
    return 0
  end
end
```

Edit sub-program

Go to Screen\_1 to create three Numeric Entry elements with the read addresses as \$100, \$101, and \$200 respectively.

Edit HMI screen

Step 1: download the project to the HMI. Set 250 for both \$100 and \$101, and the HMI displays the comparison result as 1 as shown below:

Execution results

Step 2: change the value of \$100 to 200, and the HMI displays the comparison result as 0 as shown below:
